

Standard Test Method for Rating Grain Size and Frequency of Abnormally Large Grains in Cemented Tungsten Carbides (Hardmetals)¹

This standard is issued under the fixed designation B 930; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method describes a procedure for measuring abnormally large grains and the frequency of those grains in cemented tungsten carbides (hardmetals).

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 ASTM Standards:

B 243 Terminology of Powder Metallurgy²

B 406 Test Method for Transverse Rupture Strength of Cemented Carbides²

B 657 Test Method for Metallographic Determination of Microstructure in Cemented Tungsten Carbides²

B 665 Guide for Metallographic Sample Preparation of Cemented Tungsten Carbides²

3. Terminology

3.1 *Definitions*—Definitions of powder metallurgy terms can be found in Terminology B 243.

3.2 Definitions of Terms Specific to This Standard:

3.2.1 *E-Rating*—the number/cm² of grains larger than a specified size in a fully-etched specimen.

3.2.2 *L-Rating*—the size, in μm, of the largest grain observed in a fully-etched specimen.

4. Summary of Test Method

4.1 A polished and fully etched specimen/specimens having a minimum observable area of 0.5 cm² is examined using a metallograph. Abnormally large grains, compared to the finer-grained background material, are identified. These grains are

categorized as: (1) The number of grains larger than a specified size, or (2) The largest grain observed, or both.

5. Significance and Use

5.1 The microstructure and grain growth of cemented tungsten carbides affect the material's mechanical and physical properties. The grain size and distribution will affect the material's wear resistance and fracture toughness. Abnormally large grains as compared to the background may introduce an area of weakness in a sintered part.

5.2 This test method may be used in acceptance testing of cemented tungsten carbide materials or the tungsten carbide powder used in their manufacture. The specified grain size used for the E-Rating is to be agreed upon between purchaser and supplier.

6. Apparatus

6.1 *Metallographic Microscope*, capable of magnifications of up to 1500×.

6.2 Ordinary metallurgical laboratory equipment.

6.3 Equipment for specimen preparation as outlined in Guide B 665.

7. Test Specimens

7.1 *Specimen Size*—The recommended specimen shall be the standard transverse rupture specimen as specified in Test Method B 406; that is, ground to the following dimensions: 5.00 ± 0.25 mm (0.200 ± 0.010 in) thick by 6.25 ± 0.25 mm (0.250 ± 0.010 in) wide by 19.0 mm (0.750 ± in) long. Alternatively, the specimen shall be a size to provide a minimum 0.5 cm² surface area of examination, or it may consist of several samples that provide this minimum area.

7.2 Specimen Preparation:

7.2.1 Polish the specimen/specimens according to the procedure described in Guide B 665, or other suitable metallographic polishing procedure. If using the recommended specimen, polish the 6.25 by 19.0 mm side.

7.2.2 Etch the specimen according to the procedure described in Test Method B 657, or other suitable etching procedure that will reveal the tungsten carbide grain structure.

¹ This test method is under the jurisdiction of ASTM Committee B09 on Metal Powders and Metal Powder Products and is the direct responsibility of Subcommittee B09.06 on Cemented Carbides.
